Workforce Risk Velocity

A company can become materially riskier without changing a machine, a process, a building, or a written safety rule.

Sometimes the thing that changes is the workforce itself.

A plant adds a second shift. A distribution operation wins a large contract and hires 80 people in six weeks. A construction company opens three projects at once. Experienced employees are promoted into supervision. Overtime rises because the people who know the work are also trying to teach it. Temporary labour fills the gaps. The safety program on paper may be exactly the same as it was three months earlier, but the operating risk is not.

Most loss-control systems are better at measuring what has already happened than detecting this kind of change while it is building. Incident rates, claim frequency, severity, lost days, and experience modification all matter. They are also downstream measures. By the time they move, the workforce conditions that produced the losses may have been in place for months.

> **The risk profile of a workplace can change faster than its historical loss data can show it.**

The workforce is an exposure, not just a headcount

Workers compensation is built around exposure. Payroll changes matter. Classifications matter. The kind of work being performed matters. Yet employers often treat workforce composition as an HR statistic rather than a safety and loss-control variable.

That misses an important part of the picture. Two organizations can have the same number of employees doing the same work and still carry very different levels of operational risk depending on how long those employees have been in the job, how much practical experience exists on each crew, how many supervisors are new to their role, how quickly people are being moved between jobs, and

whether training capacity has kept pace with hiring.

The latest data makes the issue difficult to dismiss. The National Safety Council's Injury Facts analysis of 2023-2024 data reports that workers with less than one year on the job represented 22.2 percent of the workforce but 33 percent of DART cases. Travelers' 2025 Injury Impact Report, based on 1.2 million workers compensation claims, found that first-year employees accounted for approximately 36 percent of injuries and 34 percent of overall claim costs during the previous five years.

Those numbers do not mean a new employee is inherently unsafe. They mean unfamiliarity has consequences. New workers are still learning equipment, pace, terminology, informal signals, escalation paths, physical demands, production expectations, and which conditions are normal versus unusual. A person may understand a rule and still lack the pattern recognition that tells an experienced employee something is beginning to go wrong.

Hiring growth can create a lagging-indicator trap

In July 2026, NCCI specifically identified renewed hiring as a workers compensation issue worth watching. Employment growth had broadened into construction, manufacturing, and transportation, and NCCI noted that more hiring could add to injury frequency because less-experienced workers were entering the workforce.

That is a useful warning for employers. A strong trailing twelve-month loss record can create confidence at precisely the moment the underlying exposure is changing.

Imagine a warehouse with 200 employees and a good three-year claim history. It adds 70 workers before peak season, promotes four experienced operators into supervisory roles, brings in agency workers, and adds weekend overtime. The historical frequency rate still looks excellent in week one. So does the experience modification. Nothing in those numbers shows that one-third of the operation is now learning the work while the people who usually coach them are stretched thinner.

The question for loss control should therefore be broader than, 'What is our current claim rate?' It should also be, 'How quickly is the environment that produces claims changing?'

Measure workforce risk velocity

Workforce risk velocity is a practical way to describe the speed at which the human side of the exposure is changing. It is not a standardized insurance metric, and it should not be presented as a predictive actuarial score. Its value is managerial: it forces the organization to look for leading conditions that can weaken controls before losses appear.

A useful dashboard does not need a complicated formula. Start with a small set

of indicators and look for movement, clustering, and combinations that deserve attention.

Indicator	Why it matters	Possible trigger for review
New-hire concentration	**A larger share of the workforce is still learning the work, site, equipment, and local expectations.**	**A rapid month-over-month increase or a crew where new workers become a large share of the team.**
Workers under 90 days tenure	**The earliest period often combines low familiarity with pressure to become productive.**	**High-risk jobs with multiple employees still inside the first 90 days.**
Supervisor span of control	**Observation, coaching, and correction weaken when one supervisor is responsible for too many developing workers.**	**New-worker growth without additional qualified supervision.**
Supervisor tenure	**A technically strong worker may still be learning how to coach, intervene, document, and manage competing priorities.**	**Multiple newly promoted supervisors leading inexperienced crews.**
Overtime and extended shifts	**Fatigue and reduced coaching capacity can compound onboarding risk.**	**Experienced employees training others while also carrying sustained overtime.**
Transfers and job changes	**Company tenure can hide task inexperience.**	**Large numbers moved into unfamiliar equipment, processes, or departments.**

Temporary or contingent labour	**Responsibility for training and hazard communication may be fragmented.**	**Rapid use of agency or contract labour to fill production gaps.**

The dangerous combination is change plus compression

Hiring alone is not the problem. Organizations hire safely every day. The risk grows when change is compressed into a short period and the systems that absorb that change do not expand with it.

Training rooms have finite capacity. Supervisors have finite attention. Qualified mentors can only watch so many people. Maintenance and housekeeping can be affected when production ramps up. Procedures may lag behind new equipment or new product. Even routine administrative processes such as issuing PPE, assigning qualifications, and verifying training can become less reliable when volume spikes.

The organization may respond by shortening orientation, grouping very different jobs into one onboarding session, relying more heavily on online completion, or allowing workers to begin tasks while field verification catches up. Each choice can look reasonable in isolation. Together they can remove layers of defence.

This is why a loss-control review during rapid growth should look at capacity, not just content. The question is not simply whether the company has an onboarding program. It is whether that program can still function at the speed at which people are entering and changing jobs.

> **Growth is not the hazard. Growth that outruns supervision, practice, and verification is.**

Tenure is useful, but it is not enough

One of the easiest mistakes is to reduce the entire issue to ‘new employees get hurt more.’ That is too simplistic and can lead to weak controls.

Tenure is a signal. It is not a diagnosis. A worker with two weeks of tenure may have 15 years of experience in the trade. A worker with 12 years at the company may be operating a new machine for the first time. A long-tenured employee can also be placed at risk when rapid hiring changes crew dynamics, workload, or supervisory responsibilities.

A better approach looks at task familiarity as well as company tenure. Ask how long the employee has performed this specific job, on this equipment, at this location, under this supervisor, and with this crew. That is closer to the real exposure.

The same logic applies to supervisors. Promoting a highly skilled operator does not instantly create an effective safety leader. The new supervisor may now be responsible for job assignment, coaching, stop-work decisions, incident response, and verifying competency while simultaneously learning how to manage people.

Watch for risk migration

Rapid workforce change can also move risk rather than simply increase it.

Experienced workers may be reassigned to train new hires, leaving other tasks with less experienced coverage. Strong supervisors may be moved to launch a new location, weakening the operation they left behind. Maintenance staff may spend more time responding to production demands and less time on preventive work. New employees may be placed on off-shifts where fewer technical resources are available.

If loss control reviews only the department receiving the new hires, it can miss the secondary exposure created elsewhere.

This is particularly important in multi-site organizations. A new operation can look well supported because the company has sent its best people to launch it. The hidden risk may be developing at the mature sites that lost those people.

Training needs to expand with the exposure

When workforce risk velocity rises, training should become more targeted rather than simply more frequent.

The first priority is role-specific onboarding for the hazards that can cause serious harm. Then the organization needs supervised practice, field verification, and reinforcement after the employee has enough experience to understand the context. The same principle applies to transferred workers and newly promoted supervisors.

This is where a learning platform can help, but completion should not be confused with competence. SafetyNow can provide a consistent training baseline, assign role-specific learning, deliver refresher content, and create centralized records across a growing workforce. The field layer still matters. Supervisors need to observe critical tasks, coach the worker, and verify that the learning survives contact with real work.

For insurers and loss-control teams, that distinction is valuable. A policyholder that can show 98 percent training completion may still need help if supervisors cannot verify competence or if onboarding capacity is being overwhelmed by growth.

A growth-triggered loss-control review

Most organizations schedule safety reviews by calendar. Workforce change gives them another trigger.

A hiring surge, acquisition, new shift, new site, large seasonal ramp, or major internal transfer should automatically prompt a focused loss-control review. It does not need to become a full audit. The purpose is to test whether the operating controls are keeping pace.

Review area	Questions to ask
Workforce mix	**What percentage of each crew is new to the company, job, equipment, or site?**
Supervision	**Has supervisor capacity increased with the number of developing workers?**
Training	**Can required training, hands-on practice, and field verification be completed before exposure?**
Mentoring	**Who is providing practical coaching, and what work are those people no longer able to do while mentoring?**
Scheduling	**Are overtime, night shifts, or production targets reducing the time available for safe learning?**
Controls	**Have procedures, PPE, guarding, traffic plans, and emergency arrangements changed with the new operating volume?**
Data	**Are near misses, first-aid cases, quality errors, equipment damage, and early-tenure events beginning to cluster?**

Loss-control professionals can see the change before the claim

Insurers are in a useful position because they can ask questions that employers may not routinely connect to workers compensation. What is the hiring plan for the next six months? Which locations are growing fastest? How many supervisors are new? Is temporary labour increasing? What proportion of high-hazard roles is being filled by people still in qualification?

Those questions can make a loss-control visit more forward-looking. They also create an opportunity to intervene before the traditional indicators deteriorate.

The goal is not to penalize growth. It is to make growth visible as an exposure change. A company adding 30 percent to its workforce should expect its safety system to do 30 percent more than it did before only if the work and workforce scale neatly. In practice, the need for coaching, verification, communication, and supervision can grow faster than headcount because so many employees are developing at the same time.

A 30-day workforce risk velocity check

Week	Action	What to learn
1	Map workforce change by site, department, shift, tenure, transfer status, and supervisor.	Where human exposure is changing fastest.
2	Compare training and supervisor capacity with the hiring or transfer rate.	Whether the system can absorb the change without compressing learning.
3	Review early signals such as first aid, near misses, equipment damage, quality errors, and coaching interventions.	Whether operational friction is appearing before recordable losses.

4	**Add controls where velocity is highest: mentoring, supervisor coverage, staggered qualification, refresher training, or temporary production limits.**	**Whether growth can continue without outrunning control capacity.**

The loss profile changes before the loss history does

Workers compensation data remains essential. It tells us what the system has produced. But an employer that waits for claims to reveal a rapidly changing exposure is using the rear-view mirror to manage acceleration.

The more useful question is what has changed in the workforce since the loss data was generated.

A hiring surge can be good news. So can a new contract, a second shift, an acquisition, or rapid expansion. None of those developments should be treated as inherently unsafe. They should be treated as changes in exposure that deserve the same discipline an organization would apply to new machinery, a new chemical, or a redesigned process.

That is the value of workforce risk velocity. It gives safety, operations, risk, and insurance professionals a way to see movement before the claim arrives.

> **A stable loss history does not guarantee a stable risk profile. Watch how quickly the workforce is changing.**

Key takeaways

- Workers with short tenure represent a disproportionate share of serious nonfatal injury cases and workers compensation claims in multiple data sets.
- Treat workforce composition, task familiarity, supervisor capacity, and hiring speed as loss-control variables.
- Do not wait for claim frequency to rise before responding to a major hiring, transfer, acquisition, or seasonal ramp.
- Measure task tenure as well as company tenure. Experienced employees can still be new to the exposure.
- Watch for risk migration when experienced workers and supervisors are moved to support growth elsewhere.
- Use training technology to create consistency and records, but retain supervised practice and field verification for critical work.
- For insurers, workforce-change questions can turn loss control from

historical review into earlier intervention.
