

Construction Demolition: Hidden Hazards Behind Every Wall Picture This

This image shows a demolition crew working inside an older commercial building where walls and ceiling sections are being removed. A worker swings a tool to break through drywall, unaware that hidden electrical wiring and weakened structural supports are directly behind the surface. Dust fills the air, debris is scattered across the floor, and overhead materials appear unstable. In demolition, what you can't see is often what injures you.

A routine tear-down can quickly turn deadly when walls conceal live power, gas lines, asbestos, or load-bearing elements that suddenly shift or collapse. Falling debris, unexpected structural failure, and struck-by hazards are constant risks when demolition is rushed or poorly assessed. Always complete a full hazard survey before starting, shut down utilities, wear proper PPE, control dust, and follow engineered demolition plans to prevent serious, preventable injuries.
